

Maryland House Districts Data Profile

2017–2021 American Community Survey 5-year Estimates

Description of the Data

What is the American Community Survey (ACS)? What are Five-Year Estimates?

The American Community Survey (ACS) is a nationwide survey designed to collect demographic, social, economic, and housing data every year. The U.S. Census Bureau releases data from the ACS in both single-year and multi-year estimates. Unlike previous Census Bureau data products, the ACS is not concerned with creating population counts, but with collecting data on population characteristics. In the past, population characteristics were collected every ten years through the “long form” of the decennial census, which was sent to a sample of the total population (approximately one in six households in 2000). The ACS replaces this form with a program that initially sampled 250,000 unique housing unit addresses per month, or 3 million per year. The sampling rate has since been increased with the 2015 ACS sampling 3.54 million unique addresses. It is important to note that after five years of accumulated sampling, the ACS still has a smaller sample size than the decennial census, which makes it critical to note margins of error associated with these estimates (see “What is a Margin of Error?” below).

A rolling sample allows population characteristics for large areas (those over 65,000 in population) to be reported yearly, instead of once every ten years under the previous “long form” system. Characteristics for areas containing less than 65,000 persons are reported as five-year period estimates. The differences from the decennial census mean that ACS data are more timely, but cannot be used to pinpoint a particular point in time (unlike the decennial census, which is specifically for April 1st of the census year). For more information on the ACS, how the data are collected, and how they should be used, refer to *A Compass for Understanding and Using American Community Survey Data: What General Data Users Need to Know* (September 2022), available online from the U.S. Census Bureau ([click here](#)).

What is a Margin of Error (MoE)?

Since the ACS is a sample of a population, the results are subject to sampling error. This error also existed in the previous “long form” but due to the larger sample size it was generally not reported by the Census Bureau. Because of the methodology and the smaller sample sizes used to create the ACS, the reported data may have larger errors than normal. The Census Bureau now reports a margin of error (MoE) based on a 90 percent confidence level that allows data users to understand the accuracy of the data and how it should be used. Generally, five-year period estimates have a smaller MoE than one-year estimates. Estimates with too few sample cases to create a reliable estimate are marked with the letter “N” in the tables. For more information on this subject, please refer to *American Community Survey Accuracy of the Data (5-year 2014-2018)*, available online from the U.S. Census Bureau ([click here](#)).

On February 1, 2022, Maryland's Legislative Districts, based on 2020 Census redistricting, took effect. The data in this handbook are for these district boundaries. These districts are displayed in the following map ([click here](#)).

Additional data for legislative districts in a profile format can be found on the Maryland Department of Planning's State Data Center web site ([click here](#)).
